

RaPDTool degrades gracefully out of domain: rank resolved tracks genomic distance

14 genomes spanning genomic distance to RaPDTool's database, equal coverage 27.7×.

No genome is assigned a confident species below the 95 % threshold; organisms below ~80 % identity are not reported at all.

Two pairs share an identity (100.0 %, 73.7 %); each pair's marks are offset vertically and its names set side by side so both are legible — neither offset carries meaning.

Rank is read from full mode, whose cutoffs are fixed: Mash distance < 0.05 -> species, 0.05-0.08 -> genus. Mash resolves the genus of the three genomes inside that window; beyond it three more are placed to genus by the FOCUS profile alone (hollow marks).
