

# Standard metagenomic databases omit most characterised type material

A Absent from competitor databases  
n = 30,209 type-material genomes

The 3,423 genomes absent from both databases (11.3 % of all type material) are the population from which the mock community's 10 conflictive genomes were drawn, stratified by phylum (one per phylum) so that no single lineage dominates the sample.

The 10 reference genomes were drawn from the 11,552 genomes present in both, as a control.

Capping Kraken2 from 103.7 GB to 8.1 GB leaves the absence rate essentially unchanged: capping removes minimizers, not taxa.

Panel B shows phyla with  $\geq 50$  genomes; 2 sampled phyla fall below that threshold and are not shown.

B The gap is taxonomically pervasive  
● = phylum sampled for the mock community
